# What the Kinect does

Get Depth Image

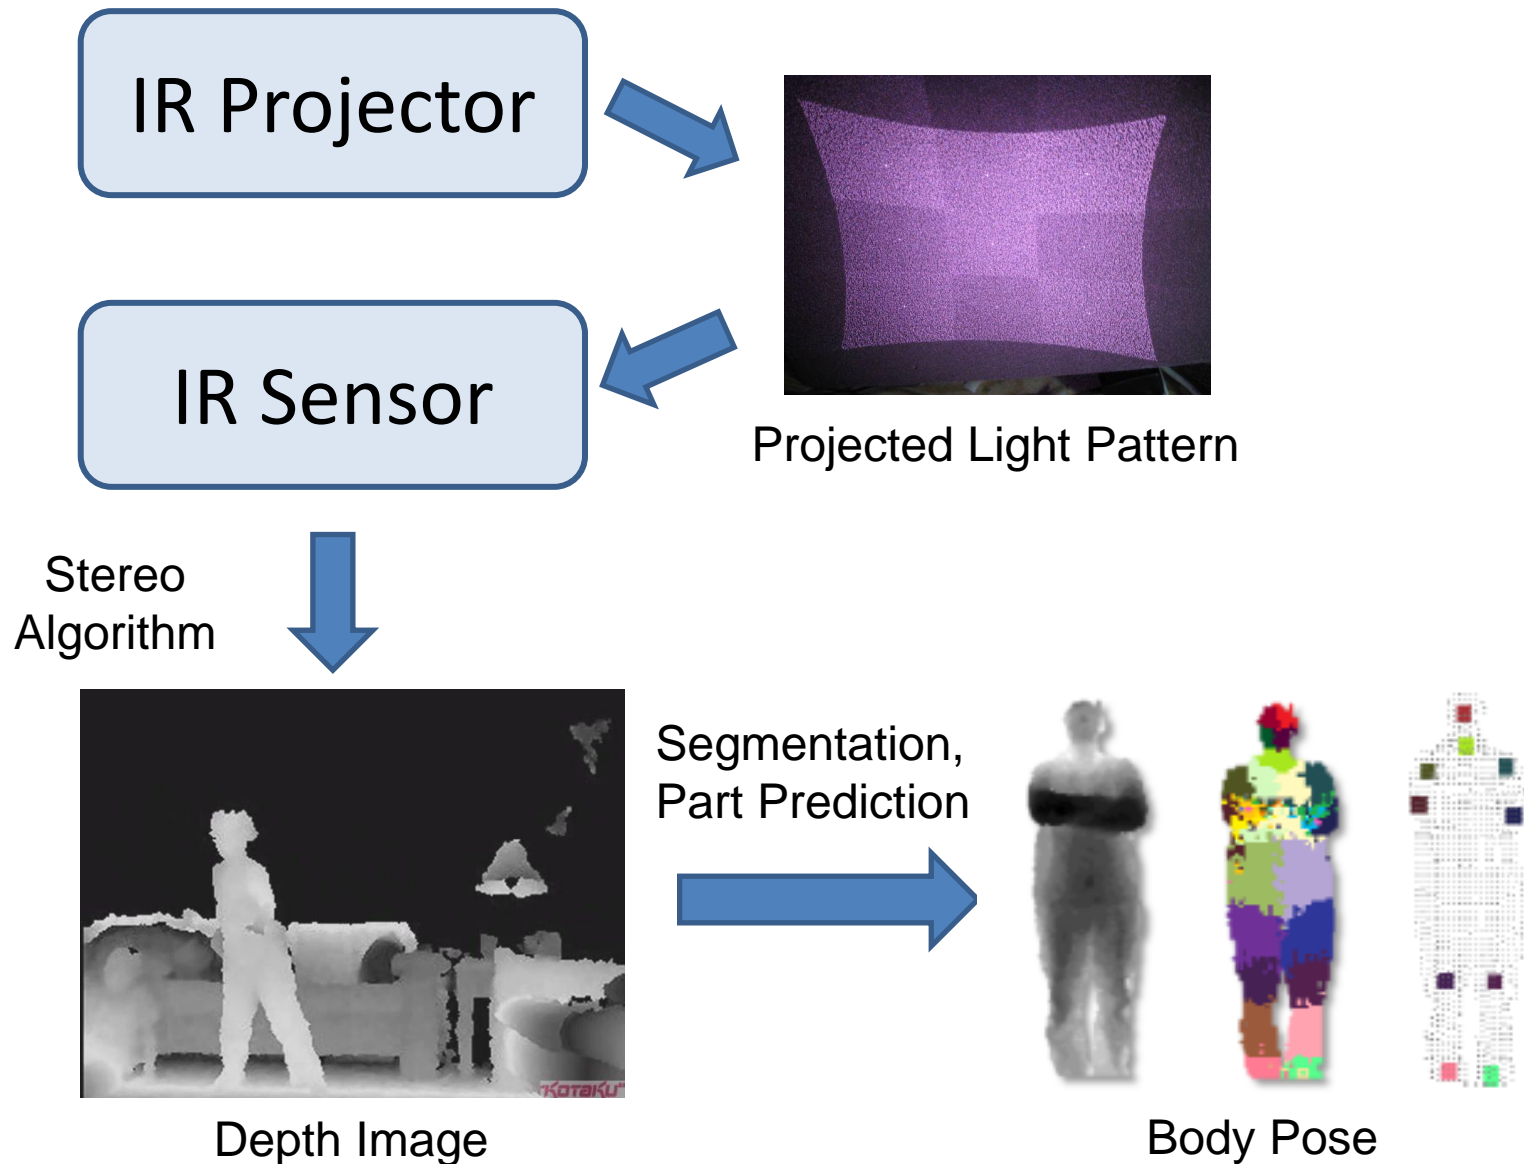

Estimate Body Pose

Application (e.g., game)

# How Kinect Works: Overview

# Part 1: Stereo from projected dots

The diagram illustrates the process of generating stereo images from projected dots. It begins with an IR Projector projecting a light pattern onto a surface, which is captured by an IR Sensor. The resulting stereo pair is processed by a Stereo Algorithm to produce a Depth Image. This depth image is then used for Segmentation and Part Prediction, leading to the final Body Pose output.

```
graph TD; IP[IR Projector] --> PLP[Projected Light Pattern]; PLP --> IS[IR Sensor]; IS -- "Stereo Algorithm" --> DI[Depth Image]; DI -- "Segmentation, Part Prediction" --> BP[Body Pose]
```

Dense depth map

# Depth from Stereo Images

- Goal: recover depth by finding image coordinate  $x'$  that corresponds to  $x$

# Stereo and the Epipolar constraint

Potential matches for  $x$  have to lie on the corresponding line  $l'$ .

Potential matches for  $x'$  have to lie on the corresponding line  $l$ .

# Simplest Case: Parallel images

- Image planes of cameras are parallel to each other and to the baseline
- Camera centers are at same height
- Focal lengths are the same
- Then, epipolar lines fall along the horizontal scan lines of the images

# Basic stereo matching algorithm

- For each pixel in the first image
  - Find corresponding epipolar line in the right image
  - Examine all pixels on the epipolar line and pick the best match
  - Triangulate the matches to get depth information

# Depth from disparity

$$\frac{x - x'}{O - O'} = \frac{f}{z}$$

$$\text{disparity} = x - x' = \frac{B \cdot f}{z}$$

Disparity is inversely proportional to depth.

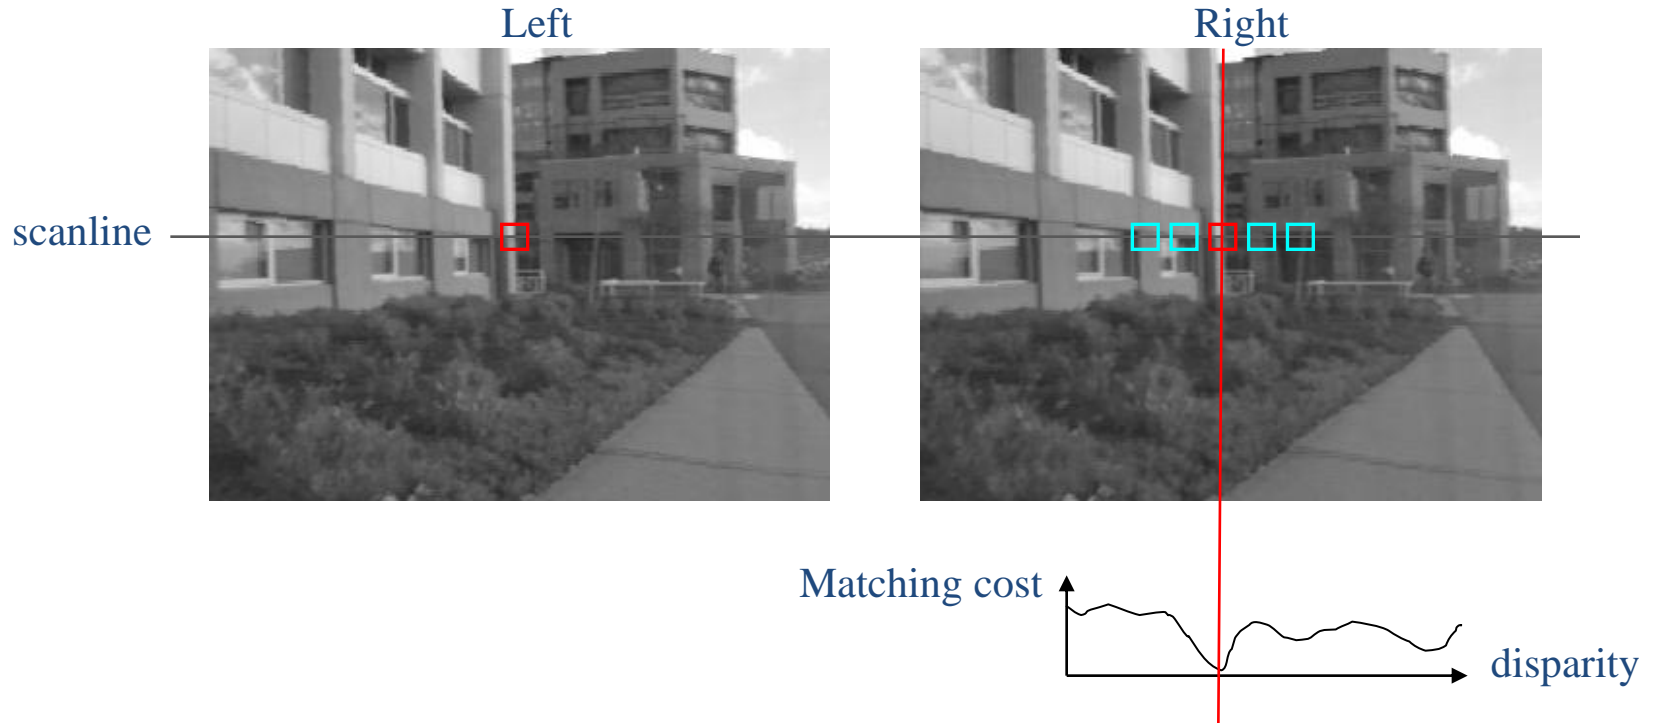

# Basic stereo matching algorithm

- If necessary, rectify the two stereo images to transform epipolar lines into scanlines
- For each pixel  $x$  in the first image
  - Find corresponding epipolar scanline in the right image
  - Examine all pixels on the scanline and pick the best match  $x'$
  - Compute disparity  $x - x'$  and set  $\text{depth}(x) = fB/(x - x')$

# Correspondence search

- Slide a window along the right scanline and compare contents of that window with the reference window in the left image
- Matching cost: SSD or normalized correlation

# Depth from Projector-Sensor

Only one image: How is it possible to get depth?

# Same stereo algorithms apply

# Example: Book vs. No Book

# Example: Book vs. No Book

# Region-growing Random Dot Matching

1. Detect dots (“speckles”) and label them unknown
2. Randomly select a region anchor, a dot with unknown depth
  - a. Windowed search via normalized cross correlation along scanline
    - Check that best match score is greater than threshold; if not, mark as “invalid” and go to 2
  - b. Region growing
    1. Neighboring pixels are added to a queue
    2. For each pixel in queue, initialize by anchor’s shift; then search small local neighborhood; if matched, add neighbors to queue
    3. Stop when no pixels are left in the queue
3. Stop when all dots have known depth or are marked “invalid”

# Projected IR vs. Natural Light Stereo

- What are the advantages of IR?
  - Works in low light conditions
  - Does not rely on having textured objects
  - Not confused by repeated scene textures
  - Can tailor algorithm to produced pattern
- What are advantages of natural light?
  - Works outside, anywhere with sufficient light
  - Uses less energy
  - Resolution limited only by sensors, not projector
- Difficulties with both
  - Very dark surfaces may not reflect enough light
  - Specular reflection in mirrors or metal causes trouble

# Part 2: Pose from depth

# Goal: estimate pose from depth image

# Challenges

- Lots of variation in bodies, orientation, poses
- Needs to be very fast (their algorithm runs at 200 FPS on the Xbox 360 GPU)

Pose Examples

Examples of one part

# Extract body pixels by thresholding depth

# Basic learning approach

- Very simple features

- Lots of data

- Flexible classifier

# Get lots of training data

- Capture and sample 500K mocap frames of people kicking, driving, dancing, etc.
- Get 3D models for 15 bodies with a variety of weight, height, etc.
- Synthesize mocap data for all 15 body types

# Body models

# Features

- Difference of depth at two offsets
  - Offset is scaled by depth at center

# Part prediction with random forests

- Randomized decision forests: collection of independently trained trees
- Each tree is a classifier that predicts the likelihood of a pixel belonging to each part
  - Node corresponds to a thresholded feature
  - The leaf node that an example falls into corresponds to a conjunction of several features
  - In training, at each node, a subset of features is chosen randomly, and the most discriminative is selected

# Joint estimation

- Joints are estimated using mean-shift (a fast mode-finding algorithm)
- Observed part center is offset by pre-estimated value

# Next week

- Tues
  - ICES forms (important!)
  - Wrap-up, proj 5 results
- Normal office hours + feel free to stop by other times on Tues, Thurs
  - Try to stop by instead of e-mail except for one-line answer kind of things
- Final project reports due Thursday at midnight
- Friday
  - Final project presentations at 1:30pm
  - If you're in a jam for final project, let me know early
